

Arrays

Define more than one variable for similar purpose

Example:

Grades of a student group – define 30 variable for them

Solution:

Define 30 variable of type double to hold the information

Is this so rational?

What is an array?

- An array is a sequence of elements
- Arrays keep variables of only one type
- The order of the elements remains the same
- Arrays have a fixed length
- The access to the elements is direct
- The elements are accessed through an index

What is an array?

Array of 10 elements

Element with value 9

*An empty element
(default value)*

← Array length is 10 →

Declaration and initialization

Declaration

Type of the array

Name of the array(variable)

```
int[] array;
```

```
int array[];
```

Initialization

Type of the array

Size of the array

```
array = new int[10];
```

Declaration and initialization

```
int[] array = new int[10];
```

```
int[] array = { 5, 7, -2, 12, 0, 4 };
```

Accessing the elements

- Elements are accessed by index
- The index of the first is 0
- The index of the last is equal to the length – 1
- The elements can be read and changed

Accessing the elements

`array[i]` returns the element with index `i`

```
System.out.println(array[0]);
```

Print the first element

```
System.out.println(array[1]);
```

Print the second element

```
array[2] = 100;
```

Change the value of the third element

More about the arrays

- `array.length` returns the length

```
System.out.println(array.length);
```

- Getting an element beyond the size will result in a runtime error

```
array[11] = 20;
```

- Usually using loop
- The most common case is using a **for** loop

```
public static void main(String[] args) {  
    int[] array = new int[10];  
    for (int i = 0; i < array.length; i++) {  
        array[i] = 7;  
    }  
}
```

- You can iterate array with **while** loop and any other

```
public static void main(String[] args) {  
    int[] array = new int[10];  
    int i = 0;  
    while (i < array.length) {  
        array[i] = 7;  
        i++;  
    }  
}
```

- The array is iterated
- The value of the current element is printed using `System.out.print()`

```
double[] array = { 2.5 ,3, 5, 8, -12.9, 7.0 };  
  
for (int i = 0; i < array.length; i++) {  
    System.out.print(array[i] + " ");  
}
```

*Add a whitespace to
separate the elements*

Reading from console

- The array is iterated
- Use scanner to read the value from the console
- Assign the read value to the current element

```
public static void main(String[] args) {  
    int[] array = new int[10];  
  
    Scanner sc = new Scanner(System.in);  
  
    for (int i = 0; i < array.length; i++) {  
        System.out.println("Enter value:");  
        array[i] = sc.nextInt();  
    }  
}
```

*Declaration and
initialization of the array*

*Create **Scanner***

*Iterate the array using **for** loop
and read the value for each element
from the console*

Comparing arrays

- Arrays are referred types and can't be compared using `==` operator
- To compare two arrays, you have to iterate them and compare their elements respectively

Try it!

```
double[] array = { 2.5 , 3, 5.8 };  
double[] array2 = new double[3];  
array2[0] = 2.5;  
array2[1] = 3;  
array2[2] = 5.8;  
...
```

Copying arrays

```
int[] newArray = oldArray;
```

is not exactly what you want

```
public static void main(String[] args) {  
    int[] oldArray = { 1, 2, 3};  
    int[] newArray = oldArray;  
  
    oldArray[0] = -10;  
    System.out.println(newArray[0]);  
}
```

What will be printed to the console?

Multidimensional Arrays

- Have more than one dimension (2, 3, 4, ...)
- The 2-dimensional arrays are called matrices
- A matrix is an array in which each element is an array

A matrix with 4 rows and 6 columns

	0	1	2	3	4	5
0	1	2	3	4	5	6
1	7	8	9	10	11	12
2	13	14	15	16	17	18
3	19	20	21	22	23	24

Creating and iterating matrix

The multidimensional arrays use the same concept as an ordinary arrays

```
public static void main(String[] args) {  
    int[][] matrix = new int[3][4];  
  
    for (int i = 0; i < matrix.length; i++) {  
        for (int j = 0; j < matrix[0].length; j++) {  
            matrix[i][j] = 10;  
        }  
    }  
  
    matrix[0][0] = 1;  
    matrix[2][3] = 100;  
}
```

*Create matrix with
3 rows and 4 columns*

*Set 1 to the element in
the upper left corner*

*Set 100 to the element in
the bottom right corner*
